

Abstract

The aim of this sub-project is to develop an image processing component to support low-cost automated greenhouses. The image processing application must enable the greenhouse system to establish various aspects about the plants from the images taken. These aspects include plant health, plant growth and plant disease identification from the images of different parts of the plants in the greenhouse.

What is the purpose of this section? To introduce background information about phenotyping in relation to plants. - What it is? - Why it is useful? - Relations to current study at hand?

My definition: Plant phenotyping falls under the larger field of plant phenomics. A phenotype is loosely a type of a phenoma specific organism may exhibit. Two different organisms may exhibit a phenotype in two drastically different ways depending on the interaction between the phenotype, environment, and the organisms genes. Phenotypical properties of organisms are multifaceted, for example plant metabolic health is a phenotype depending on the environment into terms of water, and heat which is abiotically. Additionally it might be dependent on the plants genes. Some plants might be more metabolically healthy in more humid conditions.

Definition 1: “All ‘types’ of organisms, distinguishable by direct inspection or only by finer methods of measuring or description, may be characterized as ‘phenotypes’.” [3]

Definition 2: The phenotype can be seen as the combination of all the morphological, physiological, anatomical, chemical, developmental, and behavioral characteristics that, when put together, represent the individual organism. Phenotyping, which is the process of characterizing the phenotype [2]

Definition 3: For the purposes of this review, we refer to phenotyping as the set of methodologies and protocols used to measure plant growth, architecture, and composition with a certain accuracy and precision at different scales of organization, from organs to canopies. The goal of modern plant phenotyping is to deliver quantitative data on the dynamic responses of plants to the environment. [1]

Definition 4: The broad evaluation of complex plant traits like growth, development, tolerance, resistance, architecture, physiology, ecology, and yield as well as the fundamental measurement of individual quantitative parameters that serve as the foundation for more complex traits is known as plant phenotyping [5]

Definition 5: Plant phenotyping is the comprehensive assessment of complex plant traits such as growth, development, tolerance, resistance, architecture,

physiology, ecology, yield, and the basic measurement of individual quantitative parameters that form the basis for more complex traits [4]
